(54) Title: EVAPORATOR DEVICE

(57) Abstract: A container (1) for containing a liquid (2) has a single opening (3) through which extends a porous wick (4). The wick (4) extends into the liquid (2). A portion of the wick out of the container (1) extends through a tubular shield (8) and a generally annular electric heater (9). The heater (9) is movable between the first position where the shield (8) is disposed between the heater and the wick, and a second position where the shield is not so disposed, so as to enable the supply of heat from the heater to the wick to be regulated.

WO 01/39809 A1

EVAPORATOR DEVICE

The present invention relates to an evaporator device and particularly although not exclusively to an
5 air freshener device.

One existing type of air freshener comprises a bottle, filled with a liquid perfume, which bottle is fitted with a wick which extends out of the bottle.
10 Heat is applied to the wick with an annular electrical heater causing the perfume to evaporate.

A problem with this type of air freshener is that it is not possible to regulate the rate of evaporation of
15 perfume. A modified type of air freshener which attempts to address this problem is described in Spanish Utility Model U9002819Y. In this air freshener the annular heater is movable in a direction parallel to the axis of the wick, with the aim of controlling
20 the amount of heat applied to the wick and, hence, the rate of evaporation of the perfume. However, in practice it has been found that this arrangement does not afford much regulation of the rate of evaporation. The output of the air freshener tends to be "all or
25 nothing", with very little variation in between, depending upon whether the heater overlaps or is axially displaced from the wick.

It is an object of the present invention to
30 overcome, or at least mitigate, the above mentioned problems by providing an evaporator device which enables improved regulation of the rate of evaporation of liquid.

-2-

According to the present invention there is provided an evaporator device adapted to receive a container for containing a liquid which container is provided with a wick, part of which is disposed in the container and part of which extends outside of the container, wherein the device is characterised in that it comprises a shield which partially covers the part of the wick which is outside of the container, when present, and a heater for heating the part of the wick which is outside of the container, when present, wherein the heater is relatively movable between a first relative position where the shield is disposed between the heater and wick, when present, and a second relative position where the shield is not so disposed, so as to enable the supply of heat from the heater to the wick, when present, to be regulated.

According to the present invention there is provided an evaporator device adapted to receive a container for containing a liquid which container is provided with a wick, part of which is disposed in the container and part of which extends outside of the container, and a shield which partially covers the part of the wick which is outside of the container, wherein the device is characterised in that it comprises a heater for heating the part of the wick which is outside of the container, when present, wherein the heater is relatively movable between a first relative position where the shield is disposed between the heater and wick, when present, and a second relative position where the shield is not so disposed, so as to enable the supply of heat from the heater to the wick, when present, to be regulated.

-3-

According to the present invention there is further provided an evaporator device comprising a container for containing a liquid, a wick, part of which is disposed in the container and part of which extends
5 outside of the container, a heater for heating the part of the wick which is outside of the container and a shield wherein the heater is relatively movable between a first relative position where the shield is disposed between the heater and wick and a second relative
10 position where the shield is not so disposed, so as to enable the supply of heat from the heater to the wick to be regulated.

The evaporator device is preferably used to
15 evaporate an active agent in liquid form.

Suitable solvents for the active agent include water, alkyl alcohol e.g. isopropanol or ethanol, an ether (such as monopropylene glycol methyl ether,
20 dipropylene glycol methyl ether and/or tripropylene glycol methyl ether), carbitol, a glycol (such as propyleneglycol or dipropyleneglycol).

The active agent preferably comprises a perfume and,
25 optionally, a malodour counteractant and/or an insecticide.

A suitable perfume for use in the invention comprises one or more fragrant materials such as
30 cedarwood oil, sandalwood oil, bergamot, Bulgarian rose oil, patchouli, myrrh, clove leaf oil, linalol, ethyl alcohol, terpineol, menthol, citronellal, and/or phenyl ethyl alcohol.

35

-4-

A suitable deodorant for use in the invention is one or more aroma and/or non-aroma chemicals which are known to have an action in reducing the perception of the intensity of malodours e.g. unsaturated esters, ketones, aldehydes, and/or a fragrant material e.g. citronellal and/or cedarwood oil (which is known to counteract the perception of tobacco malodour).

A suitable insecticide for use in the invention comprises one or more of natural insecticides such as a pyrethroid, nicotinoid, rotenoid and/or one or more of synthetic insecticides e.g. tetramethrin, bioallethrin, allethrin, phenthrin, a dinitrophenol, an organothiocyanate, benzene hexachloride, a polychlorinated cyclic hydrocarbon (e.g. heptachlor, aldrin and/or telodrin), and/or an organophosphorous (e.g. tetraethyl pyrophosphate).

The active agent may further comprise an antioxidant such as tocopherol, ascorbyl palmitate, butylated toluene, ascorbic acid, tert-butyl hydroquinone, beta carotene and/or a gallate. In addition the active agent may optionally comprise a UV stabiliser such as Uvinol 400.

A suitable container for the liquid is one made from a water/organic solvent insoluble material which is optionally either a plastics material for example polypropylene, HDPE (high density polyethylene), PET or Barex or, preferably, glass. A suitable wick is made from, for example, a natural or synthetic fibrous material such as cotton, fibreglass, mineral fibres, cellulose, ceramic, graphite or polyester.

-5-

The shield is preferably arranged such that it surrounds a portion of the exposed part of the wick, when present. As such it is preferred that the shield is in the form of a tube through which a portion of the exposed part of the wick may extend. The shield is preferably substantially annular in cross-section although other configurations may be employed.

The heater is preferably generally annular, defining an aperture. It is preferably arranged to be movable in a direction generally parallel to the axis of the wick, when present. When a container provided with a wick is inserted into the device, the wick preferably extends through the aperture defined by the heater.

Where the shield comprises a tube, through which a portion of the wick extends when present, the aperture through the heater is preferably of sufficient size to enable the heater to pass over the shield. As such it will be appreciated that the wick, shield and heater can be arranged so that the heater may be moved along the axis of the wick so that at one position the shield lies between the heater and wick, reducing the heat flow from the heater to the wick and at another position the heater is directly exposed to the wick to obtain maximum heat flow to the wick. In intermediate positions, the heater is partially shielded from the wick allowing the flow of heat to be regulated between the two extremes.

In order to afford even greater regulation of the amount of heat supplied to the wick, the thickness of the shield preferably varies in the direction in which relative movement of the heater can be made. The thinner the shield the more heat it will transmit and

-6-

vice versa. The thickness of the shield could vary continuously to enable continuous variation of heat flow to the wick or alternatively it could vary in steps to give a number of discrete levels.

5

The heater is preferably an electrical element formed into a ring shape, for example a torriodially wound resistor wire or a P.T.C. element; the heater may be encased in a plastics material. The heat output of the heating means is preferably suitable to give a running temperature of from 50 to 120°C, more preferably from 60 to 80°C, most preferably about 70°C.

10

The device according to the invention is preferably an electrical device. The electrical power supply is optionally either in the form of batteries or, preferably, the electrical device is adapted to be connected to an electrical power supply, e.g. a domestic mains socket.

20

Preferably the device comprises a housing which is adapted to support the heater, the housing preferably includes one or more apertures to allow the perfume or other vapour, to escape. The housing is preferably formed from a plastics material for example polypropylene.

25

In one arrangement the device and, particularly, the housing comprises the shield; preferably the shield is formed integrally with the housing. This arrangement has the advantage of being economic to manufacture as no separate component is required.

30

In another arrangement the shield is formed separately, for example as part of the container.

35

-7-

Preferably the shield forms part of a plug for retaining the wick in the container. This arrangement allows the shield to be formed from a different material to the remainder of the device. This would
5 allow the wick to be formed from a heat insulating material to give improved control over the flow of heat rather than being restricted to the material from which the housing is constructed.

10 Preferably the device is provided with an external control which regulates the relative movement of the heater. This is in order that the user is able to adjust the rate of evaporation of liquid. The control may, for example, comprise a wheel, which may
15 optionally be graduated. The device according to the invention is preferably provided with an actuating means, e.g. a switch, to control operation of the device, more preferably this actuating means forms part of the external control.

20 The provision of a shield, particularly one of varying thickness, enables improved control over the flow of heat from the heater to wick and hence the rate of evaporation of liquid, compared to known devices.
25 The invention allows the user to adjust the vapour output of the device progressively between a maximum and minimum level, for example depending on the size of room in which the device is installed.

30 In order that the invention may be more clearly understood embodiments thereof will now be described, by way of example, with reference to the accompanying drawings in which:-

-8-

Figure 1 shows a diagrammatic cross-sectional view of an evaporator device according to the invention;

Figure 2 shows a cross-sectional view of a part of a device similar to that illustrated in Figure 1 taken at right angles to the cross-section of Figure 1 to show details of the adjustor wheel;

Figure 3 shows an alternative form of plug for use in an evaporator device; and

Figure 4 shows an alternative form of shield for use in an evaporator device.

Referring to Figure 1 an evaporator device comprises a container 1 for containing a liquid 2, for example a perfume. The container 1 is formed from a plastics material, for example polypropylene. The container has a single opening 3 through which there extends a porous wick 4 which is retained in position by a plug 5 which fits snugly into the opening 3. The wick 4 extends into the liquid 2 which is absorbed by the wick 4 and diffuses along its length.

The wick 4 extends into a region generally defined by a top cover 6 of the device. The top cover 6 is also formed from a plastics material, for example polypropylene. The top cover 6 engages with the container 1 with a snap fit, although any other suitable technique could be used, for example using an adhesive or screw fastening. The top cover 6 includes apertures (not shown) to enable vapour from the wick 4 to escape.

-9-

5 The portion of the wick 4 which extends out of the container 1 and indicated generally by reference numeral 7 extends through both a tubular shield 8 and a generally annular electrical heater 9.

10 The shield 8 is generally annular in cross-section and surrounds the wick 4. The shield is formed integrally with the top cover 6, from the same material.

15 The heater 9 may be produced from any suitable components although a P.T.C. heater connected to a metal alloy and encased in a plastics material is preferred.

20 The heater 9 is mounted movably on the device to enable it to move in a direction substantially parallel to the axis of the wick 4, as shown by the arrow 10.

25 Movement of the heater is effected by an adjustor wheel 11 which is rotatably mounted on the device and may be moved as indicated by arrow 12. The adjustor wheel 11 includes two projections 13 between which the heater 9 is received. It will be appreciated therefore that rotation of the wheel 11 will result in movement of the heater along a direction substantially parallel to the axis of the wick.

30 The adjustor wheel 11 is partially exposed through the top cover 6 to enable adjustment of the heater 9 position from the outside of the device. The wheel is marked with numbers to indicate the rate of vaporization selected. Other markings could, of course, be employed. The periphery of the wheel is knurled.

-10 -

When the heater 9 is moved in a direction toward the top cover 6, away from the container 1, it will pass over the shield 8. When the shield 8 lies between the heater 9 and wick 4 it will reduce the amount of heat transmitted from the heater 9 to wick 4 to a minimum and so reduce the rate of evaporation of liquid from the wick 4.

When the heater 9 is moved in the opposite direction it can pass beyond the end of the shield 8, so that there is no obstruction to the passage of heat from the heater 9 to the wick 4. This leads to maximum transfer of heat to the wick 4 and hence maximises the rate of evaporation of liquid from the wick 4.

If the heater 9 is moved to a position between those described above then it will be partially shielded from and partially exposed to the wick 4. This will result in the rate of heat transfer to the wick 4 being somewhere between the maximum, when the heater 9 is fully exposed, and minimum, where the heater 9 is fully shielded, rates of heat transfer. The rate of heating of the wick 4 and hence rate of evaporation of liquid can be varied progressively between a maximum and minimum value. This has not been possible with existing devices.

The mechanism by which the heater may be moved is also illustrated in Figure 2. The same reference numerals are used in Figure 2 to identify similar components to those of the device illustrated in Figure 1.

-11 -

In an alternative embodiment of the device illustrated in Figure 1 the shield could be provided as an extension of the plug 3 rather than the top cover 6. A suitable alternative plug 14 is illustrated in cross-section in Figure 3, the plug comprises a shield 15, a portion 16 for engaging an opening, and a flange 17 to restrict insertion of the plug into an opening. If the plug 14 were substituted for the plug 5 shown in Figure 1 then it would be necessary to remove the shield 8.

In this arrangement it will be appreciated that when the heater 9 is moved towards the container 2 the shield 15 will be disposed between the heater 9 and wick 4 to give a minimum rate of evaporation and when the heater 9 is moved toward the cover 6 then there will be no shielding and a maximum rate of evaporation will be obtained.

An advantage of this arrangement is that the plug 14, with shield 15, may be formed from a different material to the top cover. For instance to achieve a low minimum rate of evaporation it may be desirable for the shield to be formed from a material with good thermally insulating and possibly also heat reflective properties. To make the whole top cover 6 from such a material could be inconvenient or expensive compared to producing only the plug 14 from such a material.

In another alternative arrangement the shield whether part of the top cover, plug or another component, is of varying thickness to allow different rates of heat flow from heater to wick depending upon the relative position of heater and shield.

-12 -

An example shield of varying thickness is illustrated in cross-section in Figure 4. The shield 18 has four discrete regions of different thickness. The wall thicknesses at these regions are 2, 1.5, 1 and 0.5mm. The thicker the shield the more effectively it will reduce heat transfer from the heater to the wick. Therefore when the heater is adjacent to the thicker end 19 of the shield 18 less heat will be transmitted to a wick extending through the shield than when it is adjacent to the thinner end 20 of the shield.

The provision of a shield of varying thickness allows even greater and more progressive control of the amount of heat transmitted to the wick and therefore the rate of evaporation of liquid. The shield could be of continuously varying thickness, rather than having discrete steps.

The above embodiments are described by way of example only, many variations are possible without departing from the invention.

Claims

1. An evaporator device adapted to receive a container
for containing a liquid which container is provided
5 with a wick, part of which is disposed in the container
and part of which extends outside of the container, and
a shield which partially covers the part of the wick
which is outside of the container wherein the device is
characterised in that it comprises a heater for heating
10 the part of the wick which is outside of the container,
when present, wherein the heater is relatively movable
between a first relative position where the shield is
disposed between the heater and wick, when present, and
a second relative position where the shield is not so
15 disposed, so as to enable the supply of heat from the
heater to the wick, when present, to be regulated.

2. An evaporator device adapted to receive a container
for containing a liquid which container is provided
20 with a wick, part of which is disposed in the container
and part of which extends outside of the container, and
a shield which partially covers the part of the wick
which is outside of the container, wherein the device
is characterised in that it comprises a heater for
25 heating the part of the wick which is outside of the
container, when present, wherein the heater is
relatively movable between a first relative position
where the shield is disposed between the heater and
wick, when present, and a second relative position
30 where the shield is not so disposed, so as to enable
the supply of heat from the heater to the wick, when
present, to be regulated.

3. An evaporator device comprising a container for
35 containing a liquid, a wick, part of which is disposed
in the container and part of which extends outside of
the container, a heater for heating the part of the

wick which is outside of the container and a shield wherein the heater is relatively movable between a first relative position where the shield is disposed between the heater and wick and a second relative position where the shield is not so disposed, so as to enable the supply of heat from the heater to the wick to be regulated.

4. A device according to any one of the preceding claims wherein the thickness of the shield varies in the direction in which relative movement of the heater can be made.

5. A device according to any one of the preceding claims which is provided with an external control which regulates the relative movement of the heater.

6. A device substantially as herein before described with reference to the drawings.
